Your post was very insightful, and I particularly agree with your point regarding the risks posed by 'hallucinations' and the lack of true semantic understanding in AI writing systems. This is especially critical in high-stakes domains such as healthcare, law and public policy, where factually incorrect outputs may lead to serious consequences.

Apart from this, you also mention ethical issues where AI models generate hate-filled or biased speech. Article 14 of the European AI Act emphasises the prominence of human oversight on AI high-risk tasks. However, there have already been some studies which show that human oversight may not be so effective in detecting errors or bias. Langer et al. (2023) propose the use of Signal Detection Theory (SDT). This could help quantify the effectivity of human oversight, which would in turn help inform strategies to improve error detection.

You mention copyright disputes, whereby AI models are trained on large amounts of copyrighted data. This was reflected in the Authors Guild v. OpenAI case which will now have a huge impact on the legitimate scope of AI training data usage (Gao et al., 2025). In response, systematic prevention mechanisms need to be created where researchers keep record of AI tool usage. Additionally, specialised similarity checks and source tracing systems should be introduced along with standards that regulate AI-generated creations (Gao et al., 2025).

I also agree with your observation about the potential loss of creative skills. Similarly, we've already seen the individual and social critical thinking of our students diminish (Larson et al., 2024). Rozputnia et al. (2025) recommend the phased introduction of AI technologies in education in collaboration with practical projects and traditional techniques, in order to maintain fundamental skills.

Overall, your post highlights the need for human oversight and robust governance for AI-generated content.

Hello Mansour,

[Chat to us!](#)

Your post provides a clear and well-structured overview of both the benefits and risks of AI writers across administrative and creative contexts. I particularly agree with your point regarding "hallucinations" and the risks they pose in high-stakes domains such as healthcare and law. This issue is widely recognised in recent literature, where large language models are shown to

generate confident but factually incorrect outputs, which can mislead users if not carefully monitored (Ji et al., 2022).

Building on your discussion, one key measure that could help mitigate these risks is the integration of human-in-the-loop systems, especially in sensitive applications. Rather than fully automating content generation, AI outputs could be used as drafts that require validation by domain experts. This approach aligns with recommendations by National Institute of Standards and Technology (2023), which emphasises the importance of human oversight and risk management frameworks in AI deployment.

Additionally, your point on bias is particularly important. While you mention training data as the source, a practical mitigation strategy is the use of dataset documentation and model transparency, as proposed by Gebru et al. (2021). This would allow developers and users to better understand potential biases and limitations before deploying such systems in real-world contexts.

Finally, in relation to creative writing, I agree that over-reliance on AI could reduce originality. However, it could also be argued that, when used critically, AI can act as a collaborative tool rather than a replacement, enhancing rather than diminishing creativity.

Overall, your post effectively highlights key risks, and incorporating governance measures such as human oversight and transparency could further strengthen the safe use of AI writers.
